## Sard's Theorem (with an Application)

As a preliminary, we have to talk about sets of measure 0.

**Defn:** Informally speaking,  $S \subset \mathbb{R}^n$  has measure zero iff  $\forall \varepsilon > 0$ ,  $S$  can be covered by countably many  $n$ -cubes of total volume less than  $\varepsilon$ .

**Prop:** If  $S$  has measure 0, and  $F : S \rightarrow \mathbb{R}^m$  is smooth, then  $F(S)$  has measure 0.

Proof: Based on the fact that  $C^\infty$  functions are Lipschitz on compact sets. I.e.,  $\|F(p) - F(q)\| < C \|p - q\|$  for some constant  $C \in \mathbb{R}_{>0}$ .

**Defn:** A subset  $S \subset M$  has measure zero iff  $\forall (U, \phi)$ , a coordinate chart, the set  $\phi(U \cap S) \subseteq \mathbb{R}^n$  has measure zero.

**Prop:** Equivalently,  $S$  can be covered by countably many charts  $\{(U_i, \phi_i)\}$  s.t.  $\forall i$ ,  $\phi_i(U_i \cap S)$  has measure zero.

**Thm:** (Sard's Theorem) If  $F : M \rightarrow N$  is smooth, the set of critical values of  $F$  has measure 0.

Reminder:  $q \in N$  is a regular value iff  $\forall p \in F^{-1}(p)$ ,  $F_{*,p}$  is surjective.

$q \in N$  is a critical value iff  $q$  is not a regular value.

Note: If  $q \notin \text{Im}(F)$ , then  $q$  is a regular value.

**Cor:** The set of regular values of  $F$  is dense in  $N$ . (It's the complement of a set of measure zero.) In particular, if  $F : M \rightarrow N$  is smooth, and  $\dim M < \dim N$ , then the only regular values are  $N \setminus \text{Im}(F)$ , so we conclude that  $N \setminus \text{Im}(F)$  is dense, and  $\text{Im}(F)$  has measure zero. In particular, submanifolds of nonzero codimension have measure zero.

(Recall: A set  $S$  is dense if  $\forall U$  open,  $U \cap S \neq \emptyset$ .)

## The Embedding Theorem

**Thm:** (Whitney Embedding Theorem) Let  $M$  be an  $n$ -dimensional manifold. Then  $M$  can be embedded in  $\mathbb{R}^{2n+1}$  and immersed in  $\mathbb{R}^{2n}$ . (This is the weak version.)

**Thm:**  $M$  can be embedded in  $\mathbb{R}^{2n}$ . (This is the strong version.)

Proof of the weak version: We start by embedding  $M$  into some  $\mathbb{R}^N$ . Then we successively project  $M \subset \mathbb{R}^N$  onto "good hyperplanes". The first step is to cover  $M$  with an atlas  $\{(U_i, \phi_i)\}_{i=1, \dots, k}$ . Let  $\{\chi_i\}_{i=1, \dots, k}$  be a subordinate partition of unity:  $\forall i$ ,  $\text{supp } \chi_i \subset U_i$ .

Now, define

$$\begin{aligned} \forall i, \psi_i : M &\rightarrow \mathbb{R}^n & F : M &\rightarrow \mathbb{R}^{kn+k \stackrel{\text{def}}{=} N} \\ p &\mapsto \begin{cases} \chi_i(p)\phi_i(p) & p \in U_i \\ 0 & p \notin U_i \end{cases} & p &\mapsto (\psi_1(p), \dots, \psi_k(p), \chi_1(p), \dots, \chi_k(p)) \end{aligned}$$

We claim that  $F$  is injective, and an immersion. Assume  $p, q \in M$  s.t.  $F(p) = F(q)$ .

Then  $\exists i$  s.t.  $\chi_i(p) = \chi_i(q) \neq 0$ . Thus,  $p, q \in U_i$ . So  $F(p) = F(q) \Rightarrow \psi_i(p) = \psi_i(q) \Rightarrow \phi_i(p) = \phi_i(q) \Rightarrow p = q$ .

Now, to show that  $F$  is an immersion. Assume  $v \in T_p M$  s.t.  $F_{*,p}(v) = 0$ . Again, choose  $i$  s.t.  $\chi_i(p) \neq 0$ , so  $p \in U_i$ . Then

$$0 = (\psi_i)_{*,p}(v) = d\chi_i(v)\phi_i(p) + \chi_i(p)d\phi_p(v)$$

since  $\psi_i = \chi_i \cdot \phi_i$ . But also  $d\chi_i(v) = 0$ , so  $d(\phi_i)_p(v) = 0$ , so we must have  $v = 0$  (as  $\phi_i$  is a diffeomorphism).  $\square$

The next step is lowering the dimension. Let  $\mathbb{P} = \{\ell \subseteq \mathbb{R}^N \text{ subspaces of dimension } 1\}$ .  $\forall \ell \in \mathbb{P}$ , let  $\pi_\ell : \mathbb{R}^N \rightarrow \ell^\perp$ , where  $\ell^\perp$  is the orthogonal complement (and a hyperplane). We claim that  $\exists \ell \in \mathbb{P}$  s.t.  $\pi_\ell|_M : M \rightarrow \ell^\perp$  is an embedding, provided that  $N > 2n + 1$ .

Well, we need to find an  $\ell$  s.t.  $\pi_\ell|_M$  is injective and an immersion. Consider

$$G : M \times M \setminus \{(p, p) \mid p \in M\} \rightarrow \mathbb{P} \\ \underbrace{(p, q)}_{p, q \in \mathbb{R}^N} \mapsto \mathbb{R} \underbrace{(p - q)}_{\neq 0}$$

$G$  is smooth. If  $\dim(M \times M) < \dim(\mathbb{P})$ , then  $\mathbb{P} \setminus \text{Im}(G)$  is dense, so if we pick  $\ell \in \mathbb{P} \setminus \text{Im}(G)$ , then  $\pi_\ell|_M$  is injective. Because  $\dim(M \times M) = 2n$ , and we need  $2n < N - 1$ , we require  $N > 2n + 1$ .

Now, to ensure  $\pi_\ell|_M$  is an immersion, let

$$H : SM \stackrel{\text{def}}{=} \{(p, v) \in TM \mid \|v\| = 1\} \rightarrow \mathbb{P} \\ (p, v) \mapsto \mathbb{R}v$$

We claim that if  $\ell \in \mathbb{P} \setminus \text{Im}(H)$ , then  $\pi_\ell|_M$  is an immersion. We perform a similar dimension count as before, and we get to  $N > 2n$ .  $\square$
